A constructive Galois connection between closure and interior

Francesco Ciraulo* Giovanni Sambin*

Abstract

We construct a Galois connection between closure and interior operators on a given set. All arguments are intuitionistically valid. Our construction is an intuitionistic version of the classical correspondence between closure and interior operators via complement.

In classical mathematics, the theory of closure operators and that of interior operators can be derived one from another. In fact, $\mathcal{A}$ is a closure operator if and only if its companion $-\mathcal{A}-$ (where $-$ is complementation) is an interior operator. Since passing to the companion is an involution, one derives that $\mathcal{J}$ is an interior operator if and only if $-\mathcal{J}-$ is a closure operator.

¿From an intuitionistic point of view, the picture is more complex. In fact, $-\mathcal{A}-$ is not in general an interior operator. So the notion of companion has to be defined differently. Our proposal is based on the notion of *compatibility* between two operators on subsets of a given set. We show intuitionistically that every closure operator $\mathcal{A}$ has a greatest compatible interior operator $\mathbf{J}(\mathcal{A})$. Since classically $\mathbf{J}(\mathcal{A}) = -\mathcal{A}-$, we choose $\mathbf{J}(\mathcal{A})$ as the companion of $\mathcal{A}$. Dually, the companion of an interior operator $\mathcal{J}$ is the greatest closure operator $\mathbf{A}(\mathcal{J})$ which is compatible with $\mathcal{J}$. Classically $\mathbf{A}(\mathcal{J}) = -\mathcal{J}-$.

We prove that $\mathbf{A}$ and $\mathbf{J}$ form a Galois connection between closure and interior operators on given set, that is $\mathcal{A} \subseteq \mathbf{A}(\mathcal{J})$ if and only if $\mathcal{J} \subseteq \mathbf{J}(\mathcal{A})$. Classically, this collapses to the triviality $\mathcal{A} \subseteq -\mathcal{J}-$ if and only if $\mathcal{J} \subseteq -\mathcal{A}-$.

In section 1, we start by analysing the notion of compatibility between arbitrary operators on the same set. We specialise to the case of compatibility between a closure and an interior operator in section 2. There we present the constructions of $\mathbf{A}$ and $\mathbf{J}$ and prove that they form a Galois connection.

Following [15], a set equipped with both a closure and an interior operator which are compatible is called a *basic topology*. In section 3, we introduce two classes of basic topologies: *saturated* basic topologies, in which the reduction is completely determined by the saturation, and *reduced* ones, symmetrically. We show that the Galois connection can be seen as the composition of two adjunctions between these two classes and all basic topologies.

*Dipartimento di Matematica, Università di Padova, Via Trieste, 63 - I-35121 Padova, Italy, {ciraulo,sambin}@math.unipd.it.

Classically, saturated and reduced basic topologies coincide. This is not the case intuitionistically as it is shown by a couple of counterexamples we give in section 4. Indeed, we show that each of the two inclusions between these classes is equivalent to the law of excluded middle.

The constructions we propose are impredicative. However, they can be carried on predicatively in many important cases. This topic is developed in section 5.

1 Operators on subsets and compatibility

This section contains some preliminaries about operators on subsets. The relation of *compatibility* between operators, introduced in [15], is recalled and its basic properties are studied. Compatibility between closure and interior operators will play a fundamental role in the following sections.

We write $Pow(S)$ for the collection of all subsets of a set S. An *operator on (the subsets of)* S is a map $\mathcal{O} : Pow(S) \to Pow(S)$. For future reference, we fix notation for some operators on a set S:

$$\begin{array}{rcl} id & \stackrel{def}{=} & \text{the identity map on } Pow(S), \\ - & \stackrel{def}{=} & \text{the intuitionistic pseudo-complement}, \\ const_U & \stackrel{def}{=} & \text{the operator with constant value } U \subseteq S, \\ \bot & \stackrel{def}{=} & const_\emptyset, \\ \top & \stackrel{def}{=} & const_S. \end{array} \tag{1}$$

For two operators $\mathcal{O}_1, \mathcal{O}_2$ on the same set S, we write $\mathcal{O}_1 \subseteq \mathcal{O}_2$ if $\mathcal{O}_1(U) \subseteq \mathcal{O}_2(U)$ for all $U \subseteq S$. This is clearly a partial order on the collection of all operators on S. This poset is a complete lattice and, actually, a frame (for this and other order-theoretic notions see [9], [11]). For every family $\{\mathcal{O}_i \mid i \in I\}$ of operators on S, its join $\bigvee_{i\in I} \mathcal{O}_i$ and its meet $\bigwedge_{i\in I} \mathcal{O}_i$ are constructed "pointwise":

$$(\bigvee_{i\in I} \mathcal{O}_i)W \stackrel{def}{=} \bigcup_{i\in I} (\mathcal{O}_i W) \quad \text{and} \quad (\bigwedge_{i\in I} \mathcal{O}_i)W \stackrel{def}{=} \bigcap_{i\in I} (\mathcal{O}_i W) \tag{2}$$

for all $W \subseteq S$. An operator $\mathcal{O}$ is *monotone* (or *order-preserving*) if $\mathcal{O}(U) \subseteq \mathcal{O}(V)$ whenever $U \subseteq V$; it is *idempotent* if $\mathcal{O}\mathcal{O} = \mathcal{O}$ (we use juxtaposition for composition). All operators of equation (1), except the pseudo-complement $-$, are monotone and idempotent. The two operators of equation (2) are monotone if so is each $\mathcal{O}_i$; thus monotone operators on a set form a subframe of the frame of all operators on that set.[1]

[1] On the contrary, each $\mathcal{O}_i$ being idempotent (or even monotone and idempotent) forces neither $\bigwedge_{i\in I} \mathcal{O}_i$ nor $\bigvee_{i\in I} \mathcal{O}_i$ to be idempotent too. Here are two counterexamples. Assume S is equipped with a (non discrete) topology and let int and cl be the topological interior and, respectively, closure operators on it. If $U \subseteq S$ is not open, then $int \wedge const_U$ is not idempotent (apply it to S). Similarly, $cl \vee const_V$ is not idempotent (apply it to $\emptyset$), provided that V is not closed.

We write $Fix(\mathcal{O})$ for the collection of all fixed points of the operator $\mathcal{O}$. Note that, provided that $\mathcal{O}$ is idempotent, the elements of $Fix(\mathcal{O})$ are all and only the subsets of the form $\mathcal{O}(W)$ for some $W \subseteq S$.

1.1 Compatibility

In doing mathematics intuitionistically, we need to distinguish inhabited subsets from merely non-empty ones. To this aim, as in [14, 15], we adopt the symbol $\between$ of overlap to express *inhabited* intersection between two subsets:

$$U \between V \quad \stackrel{def}{\iff} \quad (\exists a \in S)(a \in U \cap V) \tag{3}$$

for $U, V \subseteq S$. So $U \between V$ is intuitionistically stronger than, though classical equivalent to, $U \cap V \neq \emptyset$. Overlap allows us to express in a simple way the following relation between two operators.

Definition 1.1 *Let $\mathcal{O}$ and $\mathcal{O}'$ be two operators on the same set S. We say that $\mathcal{O}$ is* (left-)compatible *with $\mathcal{O}'$ (and that $\mathcal{O}'$ is* (right-)compatible *with $\mathcal{O}$) and we write $\mathcal{O} \succ \mathcal{O}'$ if*

$$\mathcal{O}U \between \mathcal{O}'V \quad \Longrightarrow \quad U \between \mathcal{O}'V \tag{4}$$

for all $U, V \subseteq S$.

If cl and int are the closure and interior operators on a topological space S, then $cl \succ int$ holds.[2] In fact, if a point a is in the closure of a set U, then every open neighborhood of a must "overlap" U. This argument is valid also intuitionistically as far as one defines clU as the set of adherent points of U. The motivation for studying the relation $\succ$ lies in the fact that it captures much of what is intuitionistically valid about the link between cl and int (see also section 2.1). In this section we prove some properties of $\succ$ in the case of arbitrary operators. The study of compatibility between closure and interior operators will be recovered in the following section.

Since $\neg(U \between V)$ is equivalent to $U \cap V = \emptyset$, the definition of $\mathcal{O} \succ \mathcal{O}'$ entails $U \cap \mathcal{O}'V = \emptyset \Rightarrow \mathcal{O}U \cap \mathcal{O}'V = \emptyset$ for all U and V. The converse holds classically, but not intuitionistically. To see this, consider the operators $--$ and $\top$. Then $U \cap \top V = \emptyset \Rightarrow --U \cap \top V = \emptyset$ holds, while $--U \between \top V \Rightarrow U \between \top V$ is tantamount to the logical formula $\neg\neg\exists x\varphi \rightarrow \exists x\varphi$.

Assuming $\mathcal{O}$ to be monotone, one can prove that $U \cap \mathcal{O}'V = \emptyset \Rightarrow \mathcal{O}U \cap \mathcal{O}'V = \emptyset$ for all U, V is equivalent to $\mathcal{O} - \mathcal{O}' \subseteq -\mathcal{O}'$ and also to $\mathcal{O}' \subseteq (-\mathcal{O}-)\mathcal{O}'$.

By an easy verification, the following hold for every set S:

$$\begin{array}{rl} id \succ \mathcal{O} & \text{for every operator } \mathcal{O}; \\ \mathcal{O} \succ id & \text{if and only if } \mathcal{O} \subseteq id; \\ const_U \succ \mathcal{O} & \text{if and only if } \mathcal{O} \subseteq -const_U (= const_{-U}); \\ \mathcal{O} \succ \bot & \text{for every operator } \mathcal{O}; \\ - \succ \mathcal{O} & \text{if and only if } \mathcal{O} = \bot. \end{array} \tag{5}$$

[2] Actually, also $int \succ cl$ holds; however this is of little interest since int is left-compatible with all operators, as it happens to every operator contained in the identity.

Classically, one also has $\mathcal{O} \succ -$ if and only if $\mathcal{O} \subseteq id$.

Lemma 1.2 *Let $\mathcal{O}$ and $\{\mathcal{O}_i \mid i \in I\}$ (for I a set) be operators on a set S. The following hold:*

1. *if $\mathcal{O} \succ \mathcal{O}_i$ for every $i \in I$, then $\mathcal{O} \succ (\bigvee_{i\in I} \mathcal{O}_i)$;*
2. *if $\mathcal{O}_i \succ \mathcal{O}$ for every $i \in I$, then $(\bigvee_{i\in I} \mathcal{O}_i) \succ \mathcal{O}$.*

PROOF: 1. Assume $\mathcal{O}U \between (\bigvee_{i\in I} \mathcal{O}_i)V = \bigcup_{i\in I}(\mathcal{O}_i V)$. Then there exists $i \in I$ such that $\mathcal{O}U \between \mathcal{O}_i V$. Since $\mathcal{O} \succ \mathcal{O}_i$, one has $U \between \mathcal{O}_i V$. A fortiori $U \between \bigcup_{i\in I} \mathcal{O}_i V$. 2. If $(\bigvee_{i\in I} \mathcal{O}_i)U \between \mathcal{O}V$, then there exists $i \in I$ such that $\mathcal{O}_i U \between \mathcal{O}V$. Since $\mathcal{O}_i \succ \mathcal{O}$, one has $U \between \mathcal{O}V$, as wished. q.e.d.

The analogous statement for intersections does not hold. As for the analogous of 1, consider the following counterexample in a classical setting (use the classically-valid characterization of compatibility): given the reals with their natural topology, one has both $(int)(cl) \succ const_{(-\infty,0]}$ and $(int)(cl) \succ const_{[0,+\infty)}$, but not $(int)(cl) \succ const_{(-\infty,0]} \cap const_{[0,+\infty)} = const_{\{0\}}$. The analogous of 2 holds for I inhabited (this follows from item 1 in the following lemma), but not for the empty intersection $\top$ (in fact, $\top \succ \mathcal{O}$ only if $\mathcal{O} = \bot$).

Lemma 1.3 *Let $\mathcal{O}$, $\mathcal{O}'$ and $\mathcal{O}''$ be operators on a set S; then the following hold:*

1. *if $\mathcal{O}'' \subseteq \mathcal{O}$ and $\mathcal{O} \succ \mathcal{O}'$, then $\mathcal{O}'' \succ \mathcal{O}'$;*
2. *if $\mathcal{O} \succ \mathcal{O}'$ and $\mathcal{O}'' \succ \mathcal{O}'$, then $\mathcal{O}\mathcal{O}'' \succ \mathcal{O}'$;*
3. *if $\mathcal{O} \succ \mathcal{O}'$, then $\mathcal{O} \succ \mathcal{O}'\mathcal{O}''$.*

PROOF: 1. If $\mathcal{O}''U \between \mathcal{O}'V$, then $\mathcal{O}U \between \mathcal{O}'V$ (because $\mathcal{O}'' \subseteq \mathcal{O}$), hence $U \between \mathcal{O}'V$ (because $\mathcal{O} \succ \mathcal{O}'$). 2. If $\mathcal{O}\mathcal{O}''U \between \mathcal{O}'V$, then $\mathcal{O}''U \between \mathcal{O}'V$ (because $\mathcal{O} \succ \mathcal{O}'$) and hence $U \between \mathcal{O}'V$ (because $\mathcal{O}'' \succ \mathcal{O}'$). 3. If $\mathcal{O}U \between \mathcal{O}'\mathcal{O}''V$, then $U \between \mathcal{O}'\mathcal{O}''V$ (because $\mathcal{O} \succ \mathcal{O}'$). q.e.d.

1.1.1 On the greatest compatible operators

For every $\mathcal{O}$, the operator $\bot$ is both the least operator which is left-compatible with $\mathcal{O}$ and the least operator which is right-compatible with $\mathcal{O}$. Now a natural question is whether the greatest left-compatible and the greatest right-compatible operators exist as well. We can easily show (by means of an intuitionistic, though impredicative proof) that the answer is affirmative.

Proposition 1.4 *For every operator $\mathcal{O}$ on a set S, both the greatest operator left-compatible and the greatest operator right-compatible with $\mathcal{O}$ exist and are denoted by $\mathbf{L}(\mathcal{O})$ and $\mathbf{R}(\mathcal{O})$, respectively.*

PROOF: Put $\mathbf{L}(\mathcal{O}) \stackrel{def}{=} \bigvee\{\mathcal{O}' \mid \mathcal{O}' \succ \mathcal{O}\}$ and $\mathbf{R}(\mathcal{O}) \stackrel{def}{=} \bigvee\{\mathcal{O}' \mid \mathcal{O} \succ \mathcal{O}'\}$; then apply lemma 1.2. q.e.d.

As a first stock of examples, the properties displayed in (5) give:

$$\mathbf{R}(id) = \top,\ \mathbf{L}(id) = id,\ \mathbf{R}(const_U) = const_{-U},\ \mathbf{L}(\bot) = \top,\ \mathbf{R}(-) = \bot. \quad (6)$$

By the very definition of $\mathbf{L}(\mathcal{O})$ and item 1 of lemma 1.3 it follows that:

$$\mathcal{O}' \succ \mathcal{O} \qquad \text{if and only if} \qquad \mathcal{O}' \subseteq \mathbf{L}(\mathcal{O})\,. \quad (7)$$

The rest of this section is devoted to finding a more explicit characterization of $\mathbf{L}(\mathcal{O})$ and $\mathbf{R}(\mathcal{O})$. We start with the former.

Proposition 1.5 *The operator* $\mathbf{L}(\mathcal{O})$ *satisfies:*

$$a \in \mathbf{L}(\mathcal{O})\,U \quad \Longleftrightarrow \quad (\forall\, V \subseteq S)(a \in \mathcal{O}V \ \Rightarrow\ U \between \mathcal{O}V) \quad (8)$$

for all $a \in S$ *and* $U \subseteq S$.

PROOF: Let $\mathbf{L}'(\mathcal{O})$ be the operator defined by the right-hand side of (8), that is, $a \in \mathbf{L}'(\mathcal{O})\,U \stackrel{def}{\Longleftrightarrow} (\forall\, V \subseteq S)(a \in \mathcal{O}V \ \Rightarrow\ U \between \mathcal{O}V)$. Then for every operator $\mathcal{O}'$, compatibility $\mathcal{O}'U \between \mathcal{O}V \Rightarrow U \between \mathcal{O}V$ (for all $U, V \subseteq S$) can be rewritten as $a \in \mathcal{O}'U\ \&\ a \in \mathcal{O}V \Rightarrow U \between \mathcal{O}V$ (for all $a \in S$ and $U, V \subseteq S$), that is, $a \in \mathcal{O}'U \Rightarrow (\forall V \subseteq S)(a \in \mathcal{O}V \Rightarrow U \between \mathcal{O}V)$ (for all $a \in S$ and $U \subseteq S$). So $\mathcal{O}' \succ \mathcal{O}$ if and only if $\mathcal{O}' \subseteq \mathbf{L}'(\mathcal{O})$. This shows that $\mathbf{L}'(\mathcal{O})$ is the greatest operator left-compatible with $\mathcal{O}$ and hence $\mathbf{L}(\mathcal{O}) = \mathbf{L}'(\mathcal{O})$, that is the claim. q.e.d.

In order to reach a more explicit description of $\mathbf{R}(\mathcal{O})$, we start with:

Definition 1.6 *For every operator* $\mathcal{O}$ *on a set* S*, we say that a subset* $Z \subseteq S$ splits $\mathcal{O}$ *if* $\mathcal{O}U \between Z \Rightarrow U \between Z$ *for all* $U \subseteq S$.

In other words, Z splits $\mathcal{O}$ if and only if $\mathcal{O} \succ const_Z$. Conversely, note that $\mathcal{O} \succ \mathcal{O}'$ if and only if $\mathcal{O}'V$ splits $\mathcal{O}$ for all $V \subseteq S$.

Lemma 1.7 *Let* $\mathcal{O}$ *be an operator on a set* S*. The collection of all subsets that split* $\mathcal{O}$ *is a sub-suplattice of* $Pow(S)$.

PROOF: We show that the union of splitting subsets is splitting too. If Z_i splits $\mathcal{O}$ for all $i \in I$, then $\mathcal{O} \succ const_{Z_i}$ for all $i \in I$, hence (lemma 1.2) $\mathcal{O} \succ (\bigvee_{i\in I} const_{Z_i}) = const_{\bigcup_{i\in I} Z_i}$; so $\bigcup_{i\in I} Z_i$ splits $\mathcal{O}$. q.e.d.

As a corollary, one gets that $\bigcup\{Z \subseteq S \mid Z \text{ splits } \mathcal{O}\}$ is the largest subset of S that splits $\mathcal{O}$.

Proposition 1.8 *The operator* $\mathbf{R}(\mathcal{O})$ *is the constant operator with value the largest subset that splits* $\mathcal{O}$.

PROOF: The constant operator with value the largest subset that splits $\mathcal{O}$ is $const_{\bigcup\{Z \mid Z \text{ splits } \mathcal{O}\}}$. This can be rewritten as $\bigvee\{const_Z \mid Z \text{ splits } \mathcal{O}\}$, that is, $\bigvee\{const_Z \mid \mathcal{O} \succ const_Z\}$. By the construction of $\mathbf{R}(\mathcal{O})$ in proposition 1.4, only the inclusion $\bigvee\{\mathcal{O}' \mid \mathcal{O} \succ \mathcal{O}'\} \subseteq \bigvee\{const_Z \mid \mathcal{O} \succ const_Z\}$ needs to be checked. So, let $\mathcal{O}'$ be such that $\mathcal{O} \succ \mathcal{O}'$; we must prove that $\mathcal{O}' \subseteq \bigvee\{const_Z \mid \mathcal{O} \succ const_Z\}$. The hypothesis $\mathcal{O} \succ \mathcal{O}'$ means that $\mathcal{O}'V$ splits $\mathcal{O}$ for all $V \subseteq S$, that is, $\mathcal{O} \succ const_{\mathcal{O}'V}$ for all $V \subseteq S$. Therefore, it is sufficient to check that $\mathcal{O}' \subseteq \bigvee\{const_{\mathcal{O}'V} \mid V \subseteq S\}$, which is trivial. q.e.d.

Note that $\mathcal{O} \succ \mathcal{O}'$ implies $\mathcal{O}' \subseteq \mathbf{R}(\mathcal{O})$ because $\mathbf{R}(\mathcal{O})$ is the greatest operator which is right-compatible with $\mathcal{O}$. The converse fails, in general (however, see (15) in proposition 2.11); here is a counterexample. Let $\mathcal{O}$ be the operator on S defined by $\mathcal{O}(U) = \{a \in S \mid U \text{ is inhabited}\}$ (classically, $\mathcal{O}(\emptyset) = \emptyset$ and $\mathcal{O}(U) = S$ otherwise). It is easy to check that S splits $\mathcal{O}$; hence $\mathbf{R}(\mathcal{O}) = const_S = \top$. If S contains at least two distinct elements a and b say, then $const_{\{b\}} \subseteq \mathbf{R}(\mathcal{O})$ but $\mathcal{O} \not\succ const_{\{b\}}$ because $\mathcal{O}(\{a\}) \between \{b\} \not\Rightarrow \{a\} \between \{b\}$.

2 A Galois connection between saturations and reductions

¿From now on, we restrict our attention to closure and interior operators. For the sake of greater generality, we adopt the following

Definition 2.1 *Let $\mathcal{A}$ and $\mathcal{J}$ be two monotone and idempotent operators on S. We say that:*

> *$\mathcal{A}$ is a* saturation*, or* (generalized) closure operator*, if it is* expansive*, that is, $id \subseteq \mathcal{A}$;*
>
> *$\mathcal{J}$ is a* reduction*, or* (generalized) interior operator*, if it is* contractive*, that is, $\mathcal{J} \subseteq id$.* [3]

Of course, the topological operators of closure and of interior are examples of saturations and reductions, respectively. However, saturations and reductions are more general notions since they usually lack some standard topological properties such as $\mathcal{J}(U \cap V) = \mathcal{J}U \cap \mathcal{J}V$ or $\mathcal{A}\emptyset = \emptyset$. Among the operators of equation (1), $\top$ is a saturation, $\bot$ a reduction and id is both a saturation and a reduction; also the double negation operator $--$ is a saturation. With no exceptions, in this paper $\mathcal{A}$ (also with subscripts) will always stand for a saturation, while $\mathcal{J}$ for a reduction.

[3] The definitions of saturation and reduction make sense also when $(Pow(S), \subseteq)$ is replaced with an arbitrary partial order. However, to be able to express the notion of compatibility one needs some extra structure, as in the notion of *overlap algebra* introduced in [15]. Almost all definitions and results in this paper can be restated in a natural way in that framework. See [4] for some of the basic facts.

A general method for constructing saturations and reductions is well-known. For any family $\mathcal{P} \subseteq Pow(S)$, let

$$\begin{aligned} \mathcal{A}_{\mathcal{P}}(U) &\stackrel{def}{=} \bigcap\{V \in \mathcal{P} \mid U \subseteq V\} \\ \mathcal{J}_{\mathcal{P}}(U) &\stackrel{def}{=} \bigcup\{V \in \mathcal{P} \mid V \subseteq U\} \end{aligned} \tag{9}$$

for all $U \subseteq S$. It is straightforward to check that $\mathcal{A}_{\mathcal{P}}$ and $\mathcal{J}_{\mathcal{P}}$ are a saturation and a reduction on S, respectively. Moreover, every saturation and every reduction can be obtained in this way, namely: $\mathcal{A} = \mathcal{A}_{Fix(\mathcal{A})}$ for every saturation $\mathcal{A}$ and $\mathcal{J} = \mathcal{J}_{Fix(\mathcal{J})}$ for every reduction $\mathcal{J}$. More precisely, it can be shown that $\mathcal{A}_{\mathcal{P}}$ is the least saturation which fixes $\mathcal{P}$ pointwise (that is, $\mathcal{P} \subseteq Fix(\mathcal{A}_{\mathcal{P}})$ and if $\mathcal{P} \subseteq Fix(\mathcal{A})$, then $\mathcal{A}_{\mathcal{P}} \subseteq \mathcal{A}$) and that $\mathcal{J}_P$ is the greatest reduction fixing $\mathcal{P}$.

Definition 2.2 *For every set S, we write $SAT(S)$ for the collection of all saturations on S and $RED(S)$ for the collection of all reductions on S.*

It is routine to prove that:

Proposition 2.3 *For every set S, we have:*

1. *for every family $\{\mathcal{A}_i\}_{i\in I}$ of saturations on S, the operator $\bigwedge_{i\in I} \mathcal{A}_i$ is a saturation too and hence $SAT(S)$ is a sub-inflattice of the collection of all operators on S;*

2. *for every family $\{\mathcal{J}_i\}_{i\in I}$ of reductions on S, the operator $\bigvee_{i\in I} \mathcal{J}_i$ is a reduction too and hence $RED(S)$ is a sub-suplattice of the collection of all operators on S.*

The identity operator id is both the bottom of $SAT(S)$ and the top of $RED(S)$. The top in $SAT(S)$ is the operator $\top$; symmetrically, the bottom in $RED(S)$ is the operator $\bot$.

The following lemma will be used several times in this paper.

Lemma 2.4 *For all $\mathcal{A}_1, \mathcal{A}_2 \in SAT(S)$ and all $\mathcal{J}_1, \mathcal{J}_2 \in RED(S)$, the following hold:*

1. $\mathcal{A}_1 \subseteq \mathcal{A}_2 \iff \mathcal{A}_2\mathcal{A}_1 = \mathcal{A}_2 \iff \mathcal{A}_1\mathcal{A}_2 = \mathcal{A}_2 \iff Fix(\mathcal{A}_2) \subseteq Fix(\mathcal{A}_1)$;

2. $\mathcal{J}_1 \subseteq \mathcal{J}_2 \iff \mathcal{J}_1\mathcal{J}_2 = \mathcal{J}_1 \iff \mathcal{J}_2\mathcal{J}_1 = \mathcal{J}_1 \iff Fix(\mathcal{J}_1) \subseteq Fix(\mathcal{J}_2)$.

PROOF: 1. If $\mathcal{A}_1 \subseteq \mathcal{A}_2$, then $\mathcal{A}_2\mathcal{A}_1 \subseteq \mathcal{A}_2$ because $\mathcal{A}_2$ is monotone and idempotent; also $\mathcal{A}_2 \subseteq \mathcal{A}_2\mathcal{A}_1$ since $\mathcal{A}_1$ is expansive and $\mathcal{A}_2$ is monotone and so $\mathcal{A}_2\mathcal{A}_1 = \mathcal{A}_2$. If $\mathcal{A}_2\mathcal{A}_1 = \mathcal{A}_2$, then $\mathcal{A}_1\mathcal{A}_2 \subseteq \mathcal{A}_2\mathcal{A}_1\mathcal{A}_2 = \mathcal{A}_2$ because $\mathcal{A}_2$ is expansive and idempotent; also $\mathcal{A}_2 \subseteq \mathcal{A}_1\mathcal{A}_2$ because $\mathcal{A}_1$ is expansive and so $\mathcal{A}_1\mathcal{A}_2 = \mathcal{A}_2$. If $\mathcal{A}_1\mathcal{A}_2 = \mathcal{A}_2$, then $\mathcal{A}_1(\mathcal{A}_2U) = \mathcal{A}_2U$ for all $U \subseteq S$, that is, $Fix(\mathcal{A}_2) \subseteq Fix(\mathcal{A}_1)$. Assume $Fix(\mathcal{A}_2) \subseteq Fix(\mathcal{A}_1)$. For all $U \subseteq S$ one has $\mathcal{A}_1U \subseteq \mathcal{A}_1\mathcal{A}_2U$ since $\mathcal{A}_2$ is expansive and $\mathcal{A}_1$ is monotone; hence $\mathcal{A}_1U \subseteq \mathcal{A}_2U$

because $\mathcal{A}_2 U$ is fixed by $\mathcal{A}_2$ and so, by assumption, it is fixed also by $\mathcal{A}_1$. 2. Similarly. q.e.d.

Note that, for every $\mathcal{A}_1$, $\mathcal{A}_2$ in $SAT(S)$, the composition $\mathcal{A}_1\mathcal{A}_2$ need not be a saturation (since it can fail to be idempotent). Actually, by using lemma 2.4 one can prove that both $\mathcal{A}_1\mathcal{A}_2$ and $\mathcal{A}_2\mathcal{A}_1$ are in $SAT(S)$ if and only if $\mathcal{A}_1\mathcal{A}_2 = \mathcal{A}_2\mathcal{A}_1$. A similar remark holds for reductions.

2.1 Compatibility between saturations and reductions

Classically, the closure and the interior operators of a topological space are linked one another by the equations $cl = -int-$ and $int = -cl-$, where $-$ is classical complement. Thus each of the two operators can be defined by means of the other. These facts are generally not true from an intuitionistic point of view. On the other hand, the relation $\succ$ of compatibility provides a more general link between closure and interior operators. In fact, as we saw after definition 1.1, $cl \succ int$ is intuitionistically valid. Classically, $cl \succ int$ is equivalent both to $cl \subseteq -int-$ and to $int \subseteq -cl-$;[4] so it expresses "half" of the usual requirement. Actually, since $int \subseteq -cl-$ is equivalent to $Fix(int) \subseteq Fix(-cl-)$ (lemma 2.4), the condition $cl \succ int$ says precisely that the topology corresponding to int is coarser (has fewer opens sets) than the topology corresponding to cl. For instance, if cl is the closure operator for the natural topology on the reals $\mathbb{R}^2$ and int_Z is the interior corresponding to the Zariski topology, then $cl \succ int_Z$.

When $\succ$ is restricted to a relation between $SAT(S)$ and $RED(S)$, the examples in (5) give:

$$\begin{array}{ll} id \succ \mathcal{J} & \text{for every reduction } \mathcal{J}; \\ \mathcal{A} \succ id & \text{if and only if } \mathcal{A} = id; \\ \top \succ \mathcal{J} & \text{if and only if } \mathcal{J} = \bot; \\ \mathcal{A} \succ \bot & \text{for every saturation } \mathcal{A}. \end{array} \tag{10}$$

For a given $\mathcal{P} \subseteq Pow(S)$, the operators $\mathcal{A}_\mathcal{P}$ and $\mathcal{J}_\mathcal{P}$ of equations (9) are in general *not* compatible. In fact, let W be an inhabited subset of a set S and consider the singleton family $\mathcal{P} = \{W\}$. Then $\mathcal{A}_\mathcal{P}\emptyset = W = \mathcal{J}_\mathcal{P} S$. So $\mathcal{A}_\mathcal{P}\emptyset \between \mathcal{J}_\mathcal{P} S$ holds but $\emptyset \between \mathcal{J}_\mathcal{P} S$ does not.

Lemma 2.5 *Let S be a set, $\mathcal{A} \in SAT(S)$ and $\mathcal{J} \in RED(\mathcal{J})$. If $\mathcal{A} \succ \mathcal{J}$, then:*

1. *$\mathcal{A}' \succ \mathcal{J}$ for all $\mathcal{A}' \in SAT(S)$ such that $\mathcal{A}' \subseteq \mathcal{A}$;*
2. *$\mathcal{A} \succ \mathcal{J}'$ for all $\mathcal{J}' \in RED(S)$ such that $\mathcal{J}' \subseteq \mathcal{J}$.*

Proof: Item 1 is just 1 of lemma 1.3. Item 2 follows from 3 of lemma 1.3 and lemma 2.4. q.e.d.

[4] Here is a proof. First, one can rewrite compatibility as $U \subseteq -intV \Rightarrow clU \subseteq -intV$. For $U = -V$, since $-V \subseteq -intV$, one gets $cl - V \subseteq -intV$ for all V. Hence $int \subseteq -cl-$, which is equivalent to $cl \subseteq -int-$. Conversely, let $U \subseteq -intV$. Then, by applying $-int-$, also $-int - U \subseteq -intV$ and hence $clU \subseteq -intV$ by the assumption $cl \subseteq -int-$.

By (10), $\bot$ is the least reduction compatible with a given saturation $\mathcal{A}$ and id is the least saturation compatible with a given reduction $\mathcal{J}$. We now face the dual problem: to find the *greatest saturation* compatible with a given $\mathcal{J}$ and the *greatest reduction* compatible with a given $\mathcal{A}$.

Definition 2.6 *Let $\mathcal{J} \in RED(S)$; when it exists, the greatest saturation compatible with $\mathcal{J}$ is denoted by $\mathbf{A}(\mathcal{J})$. Similarly, when the greatest reduction compatible with a given $\mathcal{A} \in SAT(S)$ exists, it is denoted by $\mathbf{J}(\mathcal{A})$.*

The facts in (10) show that $\mathbf{A}(id)$, $\mathbf{A}(\bot)$, $\mathbf{J}(id)$, $\mathbf{J}(\top)$ all exist and one has:

$$\mathbf{A}(id) = id\ , \quad \mathbf{A}(\bot) = \top\ , \quad \mathbf{J}(id) = id\ , \quad \mathbf{J}(\top) = \bot\ . \tag{11}$$

Remark 2.7 *Classically, $\mathbf{A}(\mathcal{J})$ and $\mathbf{J}(\mathcal{A})$ always exist. In fact $\mathbf{A}(\mathcal{J}) = -\mathcal{J}-$ because $-\mathcal{J}-$ is a saturation and, for any other saturation $\mathcal{A}$, $\mathcal{A}$ is compatible with $\mathcal{J}$ exactly when $\mathcal{A} \subseteq -\mathcal{J}-$.*[5] *Dually, $\mathbf{J}(\mathcal{A}) = -\mathcal{A}-$ because $-\mathcal{A}-$ is a reduction*[6] *and, for any other reduction $\mathcal{J}$, $\mathcal{J}$ is compatible with $\mathcal{A}$ exactly when $\mathcal{J} \subseteq -\mathcal{A}-$ (the latter condition is another classical equivalent to compatibility).*

We are going to show that $\mathbf{A}(\mathcal{J})$ and $\mathbf{J}(\mathcal{A})$ always exist also in an intuitionistic, though impredicative framework. Moreover, they can be constructed also predicatively in many interesting cases (see section 5).

2.1.1 The construction of $\mathbf{A}(\mathcal{J})$

Let $\mathcal{A}$ be a saturation and $\mathcal{J}$ be a reduction. From the equivalence (7), we know that $\mathcal{A}$ is compatible with $\mathcal{J}$ if and only if $\mathcal{A} \subseteq \mathbf{L}(\mathcal{J})$. Hence, in order to prove that $\mathbf{A}(\mathcal{J})$ exists it is sufficient to check that $\mathbf{L}(\mathcal{J})$ is a saturation.

Lemma 2.8 *For every $\mathcal{O}$, the operator $\mathbf{L}(\mathcal{O})$ is a saturation.*

PROOF: We use the characterization of $\mathbf{L}(\mathcal{O})$ provided by (8). $\mathbf{L}(\mathcal{O})$ is expansive: if $a \in U$, then $a \in \mathcal{O}V$ implies $U \between \mathcal{O}V$ for all V; so $a \in \mathbf{L}(\mathcal{O})U$. $\mathbf{L}(\mathcal{O})$ is monotone: if $U \subseteq U'$, then $U \between \mathcal{O}V$ yields $U' \between \mathcal{O}V$; so $\mathbf{L}(\mathcal{O})U \subseteq \mathbf{L}(\mathcal{O})U'$. Since $\mathbf{L}(\mathcal{O})$ is expansive, to prove that $\mathbf{L}(\mathcal{O})$ is idempotent it is sufficient to show that $a \in \mathbf{L}(\mathcal{O})\mathbf{L}(\mathcal{O})U$ implies $a \in \mathbf{L}(\mathcal{O})U$. So we assume $a \in \mathbf{L}(\mathcal{O})\mathbf{L}(\mathcal{O})U$ and $a \in \mathcal{O}V$ and we claim $U \between \mathcal{O}V$. The assumptions give $\mathbf{L}(\mathcal{O})U \between \mathcal{O}V$ and hence $U \between \mathcal{O}V$ because $\mathbf{L}(\mathcal{O}) \succ \mathcal{O}$. q.e.d.

Corollary 2.9 *For every reduction $\mathcal{J}$, the saturation $\mathbf{A}(\mathcal{J})$ exists and it is $\mathbf{A}(\mathcal{J}) = \mathbf{L}(\mathcal{J})$, that is:*

$$a \in \mathbf{A}(\mathcal{J})\,U \quad \Longleftrightarrow \quad (\forall\, V \subseteq S)(a \in \mathcal{J}V \ \Rightarrow\ U \between \mathcal{J}V) \tag{12}$$

[5] Intuitionistically, $-\mathcal{J}-$ is indeed a saturation, but it is not compatible with $\mathcal{J}$ in general. In fact, for $\mathcal{J} = id$, this would give $--$ as the corresponding saturation; now if $--$ were compatible with id, then $a \in --U$, that is $--U \between id\{a\}$, would give $U \between id\{a\}$, that is $a \in U$.

[6] Intuitionistically, $-\mathcal{A}-$ is not even contractive in general (think of the case $\mathcal{A} = id$).

(for all $a \in S$ and $U \subseteq S$). Moreover:

$$\mathcal{A} \succ \mathcal{J} \qquad \textit{if and only if} \qquad \mathcal{A} \subseteq \mathbf{A}(\mathcal{J})\,. \tag{13}$$

Equivalence (12) is nothing but the usual definition of a closure operator associated with an interior operator. In fact, it says that a point lies in the closure of a subset if and only if all its open neighbourhoods intersect that subset.

2.1.2 The construction of $\mathbf{J}(\mathcal{A})$

In the case of $\mathbf{J}(\mathcal{A})$ the situation is somewhat different. In fact, the constant operator $\mathbf{R}(\mathcal{A})$ is not a reduction since it is not contractive in general, though it is monotone and idempotent.[7] For instance, $\mathbf{J}(id) = id$ while $\mathbf{R}(id) = \top$. We can nevertheless prove the following:

Proposition 2.10 *The reduction $\mathbf{J}(\mathcal{A})$ exists for every $\mathcal{A} \in SAT(S)$.*

PROOF: Put $\mathbf{J}(\mathcal{A}) \stackrel{def}{=} \bigvee\{\mathcal{J} \in RED(S) \mid \mathcal{A} \succ \mathcal{J}\}$ and apply lemma 1.2 and proposition 2.3. q.e.d.

The explicit construction of $\mathbf{J}(\mathcal{A})$ that we are going to present has been inspired by the results in [13] (see also section 5). We are going to characterize $\mathbf{J}(\mathcal{A})(V)$ as the largest subset of V that splits $\mathcal{A}$, according to definition 1.6.

Proposition 2.11 *For every saturation $\mathcal{A}$, the reduction $\mathbf{J}(\mathcal{A})$ satisfies:*

$$a \in \mathbf{J}(\mathcal{A})\,V \quad \Longleftrightarrow \quad (\exists\, Z \subseteq S)(a \in Z \subseteq V \ \ \&\ \ Z \textit{ splits } \mathcal{A}) \tag{14}$$

(for all $a \in S$ and $V \subseteq S$). Moreover:

$$\mathcal{A} \succ \mathcal{J} \qquad \textit{if and only if} \qquad \mathcal{J} \subseteq \mathbf{J}(\mathcal{A})\,. \tag{15}$$

PROOF: Let $\mathcal{O}$ be the operator defined by the right-hand side of (14); so $\mathcal{O}V = \bigcup\{Z \subseteq V \mid Z \text{ splits } \mathcal{A}\}$. This shows that $\mathcal{O}$ is a reduction, namely $\mathcal{J}_P$ of equation (9) with respect to the family $P = \{Z \mid Z \text{ splits } \mathcal{A}\}$. Moreover, $\mathbf{J}(\mathcal{A})V = \bigcup\{\mathcal{J}V \mid \mathcal{J} \in RED(S) \text{ and } \mathcal{A} \succ \mathcal{J}\} \subseteq \bigcup\{Z \mid Z \subseteq V \text{ and } Z \text{ splits } \mathcal{A}\} = \mathcal{O}(V)$ because $\mathcal{J}V \subseteq V$ and $\mathcal{J}V$ splits $\mathcal{A}$ for all $\mathcal{J}$ such that $\mathcal{A} \succ \mathcal{J}$. Since by definition $\mathbf{J}(\mathcal{A})$ is the greatest reduction which is compatible with $\mathcal{A}$, to prove the opposite inclusion $\mathcal{O} \subseteq \mathbf{J}(\mathcal{A})$, it is sufficient to show that $\mathcal{A} \succ \mathcal{O}$. So let $\mathcal{A}U \between \mathcal{O}V$; this means that $a \in Z \subseteq V$ for some $a \in \mathcal{A}U$ and some Z that splits $\mathcal{A}$. In particular, $\mathcal{A}U \between Z$ and hence $U \between Z$; a fortiori, $U \between V$ as wished.

Equation (15) follows from the definition of $\mathbf{J}(\mathcal{A})$ and from item 2 of lemma 2.5. q.e.d.

It is easy to check that $Fix(\mathbf{J}(\mathcal{A})) = \{Z \mid Z \text{ splits } \mathcal{A}\}$, that is, the subsets that split $\mathcal{A}$ are precisely the fixed points of $\mathbf{J}(\mathcal{A})$.

[7] The equation $\mathbf{J}(\mathcal{A}) = \mathbf{R}(\mathcal{A})$ holds in the case (and, classically, only in the case) $\mathcal{A} = \bot$.

2.2 The Galois connection

An immediate consequence of the equivalences (13) and (15) is the following:

Proposition 2.12 *For every set S and for all $\mathcal{A} \in SAT(S)$ and $\mathcal{J} \in RED(S)$, the following holds:*

$$\mathcal{A} \subseteq \mathbf{A}(\mathcal{J}) \quad \Longleftrightarrow \quad \mathcal{A} \succ \mathcal{J} \quad \Longleftrightarrow \quad \mathcal{J} \subseteq \mathbf{J}(\mathcal{A})\,. \tag{16}$$

Therefore the two maps $\mathbf{A} : RED(S) \to SAT(S)$ and $\mathbf{J} : SAT(S) \to RED(S)$ form an (antitone) Galois connection [2, 12].

As with any Galois connection, we obtain:

Corollary 2.13 *The maps $\mathbf{A}$ and $\mathbf{J}$ satisfy:*

1. *$\mathbf{A}$ and $\mathbf{J}$ are antitone (that is, order-reversing);*
2. *$\mathcal{A} \subseteq \mathbf{AJ}(\mathcal{A})$ and $\mathcal{J} \subseteq \mathbf{JA}(\mathcal{J})$;*
3. *$\mathbf{AJA} = \mathbf{A}$ and $\mathbf{JAJ} = \mathbf{J}$;*
4. *$\mathbf{A}(\bigcup_i \mathcal{J}_i) = \bigcap_i \mathbf{A}(\mathcal{J}_i)$ and $\mathbf{J}(\bigcup_i \mathcal{A}_i) = \bigcap_i \mathbf{J}(\mathcal{A}_i)$.*

A consequence of 3 is that $\mathcal{A} = \mathbf{A}(\mathcal{J})$ for some $\mathcal{J}$ if and only if $\mathbf{AJ}(\mathcal{A}) = \mathcal{A}$. Dually, $\mathcal{J} = \mathbf{J}(\mathcal{A})$ for some $\mathcal{A}$ if and only if $\mathbf{JA}(\mathcal{J}) = \mathcal{J}$.

By remark 2.7, reasoning classically **AJ** and **JA** become the identity on $RED(S)$ and $SAT(S)$, respectively. So every saturation $\mathcal{A}$ is of the form $\mathbf{A}(\mathcal{J})$ and every reduction $\mathcal{J}$ is of the form $\mathbf{J}(\mathcal{A})$. This is not provable intuitionistically (see section 4).

Some other consequences of the Galois connection will be studied in the following sections.

3 Basic topologies

A set S equipped with a saturation $\mathcal{A}$ and with a reduction $\mathcal{J}$ such that $\mathcal{A} \succ \mathcal{J}$ can be seen as a generalized topological space. Following [14, 15], we put:

Definition 3.1 *A* basic topology *is a triple $(S, \mathcal{A}, \mathcal{J})$ where S is a set, $\mathcal{A} \in SAT(S)$, $\mathcal{J} \in RED(S)$ and $\mathcal{A} \succ \mathcal{J}$.*

A basic topology generalizes a topological space not only because $\mathcal{A}$ and $\mathcal{J}$ are not required to preserve finite joins and meets, respectively, but also because $\mathcal{A}$ could be smaller than that determined by $\mathcal{J}$, that is, $\mathbf{A}(\mathcal{J})$; and dually for $\mathcal{J}$.

In this section, we fix a set S and we consider the collection $\mathbf{BTop}(S)$ of all basic topologies on S. When S is fixed, we write $[\mathcal{A}, \mathcal{J}]$ for the basic topology $(S, \mathcal{A}, \mathcal{J})$. The following definition makes $\mathbf{BTop}(S)$ a partial order.

Definition 3.2 *Let* $[\mathcal{A}_1, \mathcal{J}_1]$ *and* $[\mathcal{A}_2, \mathcal{J}_2]$ *be two basic topologies on a set* S*. We say that* $[\mathcal{A}_1, \mathcal{J}_1]$ *is* coarser *than* $[\mathcal{A}_2, \mathcal{J}_2]$ *(equivalently,* $[\mathcal{A}_2, \mathcal{J}_2]$ *is* finer *than* $[\mathcal{A}_1, \mathcal{J}_1]$*), and write* $[\mathcal{A}_1, \mathcal{J}_1] \leq [\mathcal{A}_2, \mathcal{J}_2]$*, if* $\mathcal{A}_2 \subseteq \mathcal{A}_1$ *and* $\mathcal{J}_1 \subseteq \mathcal{J}_2$*.*

The terms coarser and finer are imported from general topology. They are justified by the fact that $\mathcal{J}_1 \subseteq \mathcal{J}_2$ and $\mathcal{A}_2 \subseteq \mathcal{A}_1$ mean precisely that $Fix(\mathcal{J}_1) \subseteq Fix(\mathcal{J}_2)$ and $Fix(\mathcal{A}_1) \subseteq Fix(\mathcal{A}_2)$. With respect to this partial order, $\mathbf{BTop}(S)$ becomes a suplattice where the join of a family $[\mathcal{A}_i, \mathcal{J}_i]$ is the basic topology $[\bigwedge_i \mathcal{A}_i, \bigvee_i \mathcal{J}_i]$. This is indeed a basic topology by proposition 2.3 and the fact that $\bigwedge_i \mathcal{A}_i \succ \bigvee_i \mathcal{J}_i$, which is proved as follows. If $\bigcap_i \mathcal{A}_i U \between \bigcup_i \mathcal{J}_i V$, then there exists k such that $\bigcap_i \mathcal{A}_i U \between \mathcal{J}_k V$. So $\mathcal{A}_k U \between \mathcal{J}_k V$ and hence $U \between \mathcal{J}_k V$ because $\mathcal{A}_k \succ \mathcal{J}_k$; thus $U \between \bigcup_i \mathcal{J}_i V$.

3.1 Reduced and saturated basic topologies

The suplattices $(RED(S), \subseteq)$ and $(SAT(S), \supseteq)$ can be embedded canonically in $(\mathbf{BTop}(S), \leq)$ by identifying $\mathcal{J}$ with $[\mathbf{A}(\mathcal{J}), \mathcal{J}]$ and $\mathcal{A}$ with $[\mathcal{A}, \mathbf{J}(\mathcal{A})]$. This motivates the following:

Definition 3.3 *We call* reduced *a basic topology of the form* $[\mathbf{A}(\mathcal{J}), \mathcal{J}]$ *and* saturated *one of the form* $[\mathcal{A}, \mathbf{J}(\mathcal{A})]$*.*

By (11), the basic topologies $[id, id]$ and $[\top, \bot]$ are both reduced and saturated at the same time. As a consequence, $[id, \bot]$ is an example of a basic topology which is neither reduced nor saturated. By the way, $[id, \bot]$ is also a counterexample to the implication $\mathcal{A} \succ \mathcal{J} \;\Rightarrow\; \mathbf{A}(\mathcal{J}) \succ \mathbf{J}(\mathcal{A})$.

¿From a classical point of view, by remark 2.7, a basic topology is reduced if and only if it is saturated; moreover, the following identities hold:

$$[\mathbf{A}(\mathcal{J}), \mathcal{J}] = [\mathbf{A}(\mathcal{J}), \mathbf{JA}(\mathcal{J})] \qquad \text{and} \qquad [\mathcal{A}, \mathbf{J}(\mathcal{A})] = [\mathbf{AJ}(\mathcal{A}), \mathbf{J}(\mathcal{A})]$$

for all $\mathcal{J}$ and $\mathcal{A}$. In other words, each reduction $\mathcal{J}$ represents the same basic topology as its corresponding saturation $\mathbf{A}(\mathcal{J})$. Similarly, for every saturation $\mathcal{A}$, $\mathcal{A}$ and $\mathbf{J}(\mathcal{A})$ correspond to the same basic topology. We shall see in section 4 that all this no longer holds intuitionistically.

The identity $\mathbf{AJA} = \mathbf{A}$ says that $\mathbf{A}(\mathcal{J})$ and $\mathbf{JA}(\mathcal{J})$ give rise to the same basic topology. Similarly, $\mathbf{J}(\mathcal{A})$ and $\mathbf{AJ}(\mathcal{A})$ correspond to the same basic topology because $\mathbf{JAJ} = \mathbf{J}$. Finally, provided that $\mathcal{J}$ and $\mathcal{A}$ are identified with the corresponding basic topologies, $\mathcal{J} \leq \mathcal{A}$ means precisely that $\mathcal{A} \succ \mathcal{J}$. From this perspective, lemma 2.5 follows from transitivity of $\leq$.

3.1.1 A decomposition of the Galois connection

Let I_R and I_S be the functors embedding $(RED(S), \subseteq)$ and $(SAT(S), \supseteq)$, respectively, into $\mathbf{BTop}(S)$. So $I_R(\mathcal{J}) = [\mathbf{A}(\mathcal{J}), \mathcal{J}]$ and $I_S(\mathcal{A}) = [\mathcal{A}, \mathbf{J}(\mathcal{A})]$. In the opposite direction, we consider a "forgetful" map from $\mathbf{BTop}(S)$ to $RED(S)$ which sends $[\mathcal{A}, \mathcal{J}]$ to $\mathcal{J}$ and "forgets" $\mathcal{A}$; similarly for $SAT(S)$. So we put

$U_R([\mathcal{A},\mathcal{J}]) = \mathcal{J}$ and $U_S([\mathcal{A},\mathcal{J}]) = \mathcal{A}$. Then $U_R : (\mathbf{BTop}(S), \leq) \to (RED(S), \subseteq)$ and $U_S : (\mathbf{BTop}(S), \leq) \to (SAT(S), \supseteq)$ are trivially monotone, and hence functors.

Proposition 3.4 *The functor U_R is right adjoint to the embedding I_R. Dually, U_S is left adjoint to I_S. In symbols, $I_R \dashv U_R$ and $U_S \dashv I_S$.*

$$\big(RED(S), \subseteq\big) \quad \underset{U_R}{\overset{I_R}{\rightleftarrows}} \quad \mathbf{BTop}(S) \quad \underset{I_S}{\overset{U_S}{\rightleftarrows}} \quad \big(SAT(S), \supseteq\big)$$

Proof: We must prove that

$$[\mathbf{A}(\mathcal{J}), \mathcal{J}] \leq [\mathcal{A}', \mathcal{J}'] \iff \mathcal{J} \subseteq \mathcal{J}' \quad \text{and} \quad \mathcal{A}' \supseteq \mathcal{A} \iff [\mathcal{A}', \mathcal{J}'] \leq [\mathcal{A}, \mathbf{J}(\mathcal{A})]$$

for all $\mathcal{J} \in RED(S)$, $\mathcal{A} \in SAT(S)$ and $[\mathcal{A}', \mathcal{J}'] \in \mathbf{BTop}(S)$. We check the latter; the former has a dual proof. From $\mathcal{A}' \supseteq \mathcal{A}$ one has $\mathbf{J}(\mathcal{A}') \subseteq \mathbf{J}(\mathcal{A})$ because $\mathbf{J}$ is antitone; from $\mathcal{A}' \succ \mathcal{J}'$ one has $\mathcal{J}' \subseteq \mathbf{J}(\mathcal{A}')$ and hence $\mathcal{J}' \subseteq \mathbf{J}(\mathcal{A})$. Together with $\mathcal{A}' \supseteq \mathcal{A}$, this gives the claim $[\mathcal{A}', \mathcal{J}'] \leq [\mathcal{A}, \mathbf{J}(\mathcal{A})]$. The other direction is trivial. q.e.d.

The composition of the two adjunctions gives: $U_S\, I_R \dashv U_R\, I_S$ between $(RED(S), \subseteq)$ and $(SAT(S), \supseteq)$. By unfolding definitions, one sees that this is nothing but the Galois connection between $\mathbf{A}$ and $\mathbf{J}$.

3.1.2 Reduction and saturation of a basic topology

Let us consider the following monotone maps on $\mathbf{BTop}(S)$:

$$(\ )^R \quad \stackrel{def}{=} \quad I_R\, U_R \quad \text{and} \quad (\ )^S \quad \stackrel{def}{=} \quad I_S\, U_S\ .$$

By unfolding definitions, one gets:

$$[\mathcal{A},\mathcal{J}]^R = [\mathbf{A}(\mathcal{J}), \mathcal{J}] \quad \text{and} \quad [\mathcal{A},\mathcal{J}]^S = [\mathcal{A}, \mathbf{J}(\mathcal{A})]$$

for every basic topology $[\mathcal{A},\mathcal{J}]$. We call these "the reduction" and "the saturation" of the basic topology $[\mathcal{A},\mathcal{J}]$. The following is a standard consequence of the adjunctions in proposition 3.4.

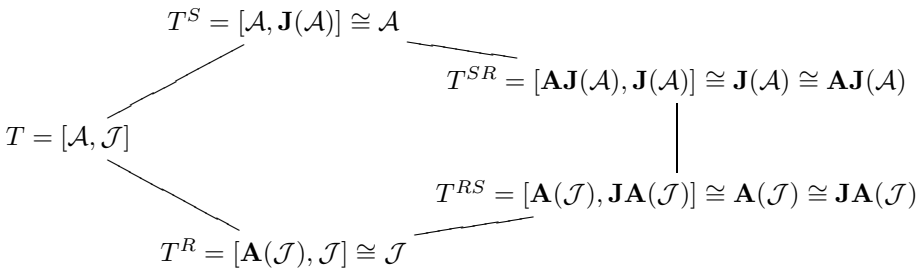
Corollary 3.5 *The endofunctors $(\ )^R$ and $(\ )^S$ are, respectively, a reduction (comonad) and a saturation (monad) on the poset $\mathbf{BTop}(S)$.*

In particular, for every basic topology $[\mathcal{A},\mathcal{J}]$ one has:

$$[\mathcal{A},\mathcal{J}]^R = [\mathbf{A}(\mathcal{J}), \mathcal{J}] \ \leq\ [\mathcal{A},\mathcal{J}] \ \leq\ [\mathcal{A}, \mathbf{J}(\mathcal{A})] = [\mathcal{A},\mathcal{J}]^S\ .$$

If $T = [\mathcal{A},\mathcal{J}]$, then T^R is the greatest reduced basic topology below T, while T^S is the least saturated basic topology above T. Clearly, T is reduced if and only if $T = T^R$; similarly, T is saturated if and only if $T = T^S$.

The following picture presents the general form of the lattice freely generated by a basic topology T with respect to the operations $(\ )^R$ and $(\ )^S$. We here write $\cong$ between two objects which are equal (when they are seen) as basic topologies.



In fact, T^S, T^{SR} and T^{RS} are always saturated (because $\mathbf{J} = \mathbf{JAJ}$), so that any further application of $(\ )^S$ on them gives no new result. Dually, T^R, T^{SR} and T^{RS} are kept fixed by $(\ )^R$ since they are all reduced. All inclusions are fairly obvious. For instance, to prove $T^{RS} \leq T^{SR}$, start from $\mathcal{A} \subseteq \mathbf{A}(\mathcal{J})$ and $\mathcal{J} \subseteq \mathbf{J}(\mathcal{A})$ (compatibility in T); then apply $\mathbf{J}$ and $\mathbf{A}$, respectively, to get (by item 1 of corollary 2.13) $\mathbf{JA}(\mathcal{J}) \subseteq \mathbf{J}(\mathcal{A})$ and $\mathbf{AJ}(\mathcal{A}) \subseteq \mathbf{A}(\mathcal{J})$.

If T is reduced (that is $\mathcal{A} = \mathbf{A}(\mathcal{J})$), not only $T = T^R$, but also $T^{RS} = T^S$ and hence $T^{RS} = T^{SR} = T^S$. Therefore when T is reduced the picture above collapses to $T \leq T^S$. Dually, if T is saturated, then $T = T^S$ and $T^R = T^{RS} = T^{SR}$. Hence when T is saturated the picture becomes $T^R \leq T$.

¿From a classical point of view one has (see remark 2.7): $T^R = [-\mathcal{J}-, \mathcal{J}]$ and $T^S = [\mathcal{A}, -\mathcal{A}-]$. So the picture above simplifies to $T^{RS} = T^R \leq T \leq T^S = T^{SR}$.

The basic topology $T = [id, \bot]$ provides a counterexample to all of the following equations: $T^R = T$, $T = T^S$ and $T^{RS} = T^{SR}$. In fact, thanks to equations (11) we get $T^R = [\top, \bot] = T^{RS}$ and $T^S = [id, id] = T^{SR}$. In section 4 we will give counterexamples to the (classically valid) equations $T^R = T^{RS}$ ("every reduced basic topology is saturated") and $T^S = T^{SR}$ ("every saturated basic topology is reduced").

4 Some counterexamples

Contrary to what happens classically, we are going to show that the classes of reduced and of saturated basic topologies are not equal intuitionistically. Actually, neither of the two classes contains the other. We begin by showing several equivalent manifestations of the two inclusions.

Proposition 4.1 *The following are equivalent:*

1. *every saturated basic topology is reduced;*

2. $T^{SR} = T^S$, *for every basic topology* T;

3. $\mathbf{AJ}(\mathcal{A}) = \mathcal{A}$, *for every* $\mathcal{A} \in SAT(S)$;

4. $\mathbf{A}$ *is surjective (every* $\mathcal{A}$ *is of the form* $\mathbf{A}(\mathcal{J})$ *for some* $\mathcal{J}$*);*

5. $\mathbf{J}$ *is injective (*$\mathbf{J}(\mathcal{A}) = \mathbf{J}(\mathcal{A}')$ *only if* $\mathcal{A} = \mathcal{A}'$*).*

Dually, also the following are equivalent:

1. *every reduced basic topology is saturated;*

2. $T^{RS} = T^R$, *for every basic topology* T;

3. $\mathbf{JA}(\mathcal{J}) = \mathcal{J}$, *for every* $\mathcal{J} \in RED(S)$;

4. $\mathbf{J}$ *is surjective (every* $\mathcal{J}$ *is of the form* $\mathbf{J}(\mathcal{A})$ *for some* $\mathcal{A}$*);*

5. $\mathbf{A}$ *is injective (*$\mathbf{A}(\mathcal{J}) = \mathbf{A}(\mathcal{J}')$ *only if* $\mathcal{J} = \mathcal{J}'$*).*

PROOF: We prove only the first half of the statement, since the other half is dual. (1⇔2⇔3): a basic topology is saturated iff it is of the form $T^S = [\mathcal{A}, \mathbf{J}(\mathcal{A})]$ for some T; so 1 holds iff every T^S is reduced iff every T^S coincides with its reduction T^{SR}, that is 2, which means that every $[\mathcal{A}, \mathbf{J}(\mathcal{A})]$ coincides with $[\mathbf{AJ}(\mathcal{A}), \mathbf{J}(\mathcal{A})]$, which is equivalent to 3. (3⇔4⇔5): this holds for every Galois connection, since it follows from corollary 2.13. q.e.d.

4.1 Not every closure is determined by an interior

We show that not every $\mathcal{A}$ is of the form $\mathbf{A}(\mathcal{J})$ for some $\mathcal{J}$, that is item 4 of the first part of proposition 4.1. We actually give a counterexample for its equivalent formulation in item 3.

Lemma 4.2 *For every set* S *and every* $\mathcal{J} \in RED(S)$*, the following holds*

$$\big(a \in \mathcal{J}S \Rightarrow a \in \mathbf{A}(\mathcal{J})U\big) \Longrightarrow a \in \mathbf{A}(\mathcal{J})U \tag{17}$$

for all $a \in S$ *and* $U \subseteq U$*.*

PROOF: Assume $a \in \mathcal{J}S \Rightarrow a \in \mathbf{A}(\mathcal{J})U$. The claim is $a \in \mathcal{J}V \Rightarrow U \between \mathcal{J}V$ for all $V \subseteq S$. So let $a \in \mathcal{J}V$. Then we immediately have $a \in \mathcal{J}S$ and hence $a \in \mathbf{A}(\mathcal{J})U$ by the assumption. By definition of $\mathbf{A}(\mathcal{J})$ we obtain that $a \in \mathcal{J}V \Rightarrow U \between \mathcal{J}V$; hence the claim $U \between \mathcal{J}V$ because $a \in \mathcal{J}V$. q.e.d.

Proposition 4.3 *The fact that* $\mathbf{AJ}$ *is the identity on* $SAT(S)$ *for every* S *is equivalent to the law of excluded middle.*

PROOF: Fix an arbitrary proposition p, let $S = \{*\}$ (the one-element set) and put $\mathcal{A}U = U \cup \{x \in S \mid p\}$ for every $U \subseteq S$. This obviously defines a saturation. We claim that the assumption $\mathcal{A} = \mathbf{AJ}(\mathcal{A})$ yields $\neg\neg p \to p$. Assuming $\mathcal{A} = \mathbf{AJ}(\mathcal{A})$, the previous lemma would give in particular $(* \in \mathbf{J}(\mathcal{A})S \Rightarrow * \in \mathcal{A}\emptyset) \Rightarrow * \in \mathcal{A}\emptyset$. By definition, $* \in \mathcal{A}\emptyset$ is equivalent to p. On the other hand, $* \in \mathbf{J}(\mathcal{A})S$ is $\exists Z(* \in Z \subseteq S \;\&\; Z \text{ splits } \mathcal{A})$, that is, $\{*\}$ splits $\mathcal{A}$. This means that $* \in \mathcal{A}U \Rightarrow * \in U$ for all $U \subseteq S$; in other words, it says that $\mathcal{A}U \subseteq U$ for all U. By the definition of $\mathcal{A}$, this is equivalent to $\{x \in S \mid p\} \subseteq U$ for all U and hence to $\{x \in S \mid p\} \subseteq \emptyset$, that is, $\neg p$. So $(* \in \mathbf{J}(\mathcal{A})S \Rightarrow * \in \mathcal{A}\emptyset) \Rightarrow * \in \mathcal{A}\emptyset$ is tantamount to $(\neg p \to p) \to p$ which is in turn equivalent to $\neg\neg p \to p$, since $(\neg p \to p) \leftrightarrow \neg\neg p$. q.e.d.

An alternative argument to show that not every $\mathcal{A}$ is of the form $\mathbf{A}(\mathcal{J})$ uses a result in [5]. There the authors construct a class of saturations and show (corollary 3) that Markov's principle follows from the hypothesis that all such saturations admit a *positivity predicate*.[8] If every $\mathcal{A}$ were of the form $\mathbf{A}(\mathcal{J})$ for some $\mathcal{J}$, then by lemma 4.2 we would obtain an expression, in the present framework, of the fact that $\mathcal{A}$ admits a positivity predicate.

4.2 Not every interior is determined by a closure

We show that not every $\mathcal{J}$ is of the form $\mathbf{J}(\mathcal{A})$ for some $\mathcal{A}$ by giving a counterexample for its equivalent formulation $\mathcal{J} = \mathbf{JA}(\mathcal{J})$.

Recall that $\mathcal{J} = \mathbf{JA}(\mathcal{J})$ holds iff $\mathbf{JA}(\mathcal{J}) \subseteq \mathcal{J}$ iff $Fix(\mathbf{JA}(\mathcal{J})) \subseteq Fix(\mathcal{J})$ iff, by the remark after proposition 2.11, $\{Z \subseteq S \mid Z \text{ splits } \mathbf{A}(\mathcal{J})\} \subseteq Fix(\mathcal{J})$. Therefore, to show that the identity $\mathcal{J} = \mathbf{JA}(\mathcal{J})$ cannot hold intuitionistically for all $\mathcal{J}$, it is sufficient to find a set S, a reduction $\mathcal{J}$ on S and a subset $Z \subseteq S$ which splits $\mathbf{A}(\mathcal{J})$ and such that the equality $Z = \mathcal{J}Z$ cannot hold intuitionistically. In fact, we will show that if the identity under consideration were true, then the law of excluded middle would hold.

Let $S = \{a, b\}$ with $a \neq b$. For every proposition p, we consider the map $\mathcal{J}_p : Pow(S) \to Pow(S)$ defined by:

$$x \in \mathcal{J}_p U \overset{def}{\iff} x \in U \;\;\&\;\; \big(b \notin U \Rightarrow p\big) \tag{18}$$

for every $U \subseteq S$ and $x \in S$. In particular, by intuitionistic logic, one gets $b \in \mathcal{J}_p U$ iff $b \in U$.

Lemma 4.4 *For every proposition p, the map $\mathcal{J}_p$ is a reduction on $\{a, b\}$.*

PROOF: The inclusion $\mathcal{J}_p U \subseteq U$ holds trivially for all $U \subseteq S$. Given this, it is sufficient to check that $\mathcal{J}_p U \subseteq V$ implies $\mathcal{J}_p U \subseteq \mathcal{J}_p V$ for all $U, V \subseteq S$. So we assume $x \in \mathcal{J}_p U \subseteq V$, for $x \in S$, and we show $x \in \mathcal{J}_p V$, that is, $x \in V$ and $b \notin V \Rightarrow p$. The former follows easily from $x \in \mathcal{J}_p U \subseteq V$. To prove the latter, first note that $b \notin V$ implies $b \notin U$. In fact, if it were $b \in U$, then it would

[8] This is linked to the well-known fact that intuitionistically not all locales are open.

also be $b \in \mathcal{J}_p U$ and hence $b \in V$ by the hypothesis $\mathcal{J}_p U \subseteq V$; a contradiction. Therefore $b \notin U \Rightarrow p$ yields $b \notin V \Rightarrow p$. But $b \notin U \Rightarrow p$ is part of the hypothesis $x \in \mathcal{J}_p U$. This completes the proof. q.e.d.

Now we choose the subset $Z = \{a\}$ and show that Z splits $\mathbf{A}(\mathcal{J}_p)$ but cannot be proven to equal $\mathcal{J}_p Z$.

Lemma 4.5 *$\{a\} = \mathcal{J}_p\{a\}$ holds if and only if p is true.*

PROOF: $\{a\} = \mathcal{J}_p\{a\}$ iff $\{a\} \subseteq \mathcal{J}_p\{a\}$ iff $a \in \mathcal{J}_p\{a\}$ which, by definition, means $a \in \{a\}$ & $(b \notin \{a\} \Rightarrow p)$ which is equivalent to p since $b \neq a$. q.e.d.

¿From now on we restrict p to be a proposition such that $\neg\neg p$ holds. For example, one can choose p of the form $\varphi \vee \neg\varphi$.

Lemma 4.6 *The subset $\{a\}$ splits $\mathbf{A}(\mathcal{J}_p)$ for every p such that $\neg\neg p$ holds.*

PROOF: Recall that $\{a\}$ splits $\mathbf{A}(\mathcal{J}_p)$ if $(\forall U \subseteq S)(\mathbf{A}(\mathcal{J}_p)U \between \{a\} \Rightarrow U \between \{a\})$, that is, $(\forall U \subseteq S)(a \in \mathbf{A}(\mathcal{J}_p)U \Rightarrow a \in U)$. Let $U \subseteq S$ and $a \in \mathbf{A}(\mathcal{J}_p)U$; our claim is $a \in U$. By (12), $a \in \mathbf{A}(\mathcal{J}_p)U$ means that $a \in \mathcal{J}_p V \Rightarrow U \between \mathcal{J}_p V$ for all $V \subseteq S$. By specializing to the case $V = \{a\} \cup V_b$ where $V_b \stackrel{def}{=} \{x \in \{b\} \mid a \in U\}$, we get:

$$a \in \mathcal{J}_p(\{a\} \cup V_b) \quad \Longrightarrow \quad U \between \mathcal{J}_p(\{a\} \cup V_b)\,. \tag{19}$$

Note that $b \notin \{a\} \cup V_b \Rightarrow p$ iff $b \notin V_b \Rightarrow p$ iff $a \notin U \Rightarrow p$. Therefore the antecedent of (19), that is $a \in \{a\} \cup V_b$ & $(b \notin \{a\} \cup V_b \Rightarrow p)$, is equivalent to $a \notin U \Rightarrow p$. On the other hand, the consequent of (19) implies that $U \between \{a\} \cup V_b$ and so $U \between \{a\}$ or $U \between V_b$. In either case, one can derive $a \in U$. Therefore (19) yields

$$(a \notin U \Rightarrow p) \Rightarrow a \in U\,. \tag{20}$$

Recall that our aim is to prove $a \in U$. Assume $a \notin U$. Then (20) becomes $p \Rightarrow a \in U$. Together with $a \notin U$, this gives $\neg p$, thus contradicting the fact that $\neg\neg p$ holds. So $a \notin U$ must be false; hence the antecedent of (20) becomes true and we are done. q.e.d.

By putting all lemmas together, we have

Proposition 4.7 *The fact that* **JA** *is the identity on $RED(S)$ for every S is equivalent to the law of excluded middle.*

PROOF: Assume $\neg\neg p$. Chose $S = \{a, b\}$ and construct $\mathcal{J}_p$ as above. Then $\{a\}$ splits $\mathbf{A}(\mathcal{J}_p)$, that is, $\{a\} \in Fix(\mathbf{JA}(\mathcal{J}_p))$. If **JA** were the identity, then $\{a\} = \mathcal{J}_p\{a\}$. So p would be true. q.e.d.

In [8], Grayson shows that there exists a model for intuitionistic analysis in which real numbers can be equipped with two different topologies, hence two different reductions, $\mathcal{J}_1$ and $\mathcal{J}_2$ say, which are associated with the same closure operator (saturation). Since the notion of closure associated with $\mathcal{J}$ in [8] is precisely our $\mathbf{A}(\mathcal{J})$, one thus has $\mathbf{A}(\mathcal{J}_1) = \mathbf{A}(\mathcal{J}_2)$, even if $\mathcal{J}_1 = \mathcal{J}_2$ does not hold. So **A** cannot be proven to be injective.

A third argument makes use of two notions of sobriety for a topological space. One can show (see [15]) that if every reduced basic topology is saturated, then the two notions coincide, while this does not hold constructively (see [1, 7]).

Remark 4.8 *As a consequence of propositions 4.3 and 4.7, all conditions in both parts of proposition 4.1 are equivalent to the law of excluded middle, and hence they are also equivalent one another.*

5 Generated and representable basic topologies

In this final section we show that the functors **A** and **J** can be defined predicatively on a wide class of reductions and saturations, respectively. Impredicatively, such classes coincide with the class of all reductions and of all saturations.

5.1 Representable basic topologies

For every binary relation r between two sets X and S, the operators $r : Pow(X) \to Pow(S)$ of *direct image* and $r^- : Pow(S) \to Pow(X)$ of *inverse image* are defined by

$$rD \stackrel{def}{=} \{a \in S \mid (\exists\, x \in D)(x\, r\, a)\} \quad \text{and} \quad r^-U \stackrel{def}{=} \{x \in X \mid (\exists\, a \in U)(x\, r\, a)\}$$

for all $D \subseteq X$ and $U \subseteq S$. Since r and r^- preserve unions, they admit right adjoints given by

$$r^*U \stackrel{def}{=} \{x \in X \mid r\{x\} \subseteq U\} \text{ and } r^{-*}D \stackrel{def}{=} \{a \in S \mid r^-\{a\} \subseteq D\}\ .$$

The fact that the operators r and r^- come from the same relation is expressed "algebraically" by:

$$rD \between U \quad \Longleftrightarrow \quad D \between r^-U \tag{21}$$

(for all $D \subseteq X$ and $U \subseteq S$). We shall refer to this condition as $r \cdot|\cdot\, r^-$, read "r and r^- are symmetric".[9]

Proposition 5.1 *For every binary relation r between two sets X and S, the structure $(S, r^{-*}r^-, rr^*)$ is a basic topology.*

Proof: Since $r \dashv r^*$ and $r^- \dashv r^{-*}$, it follows that rr^* is a reduction and $r^{-*}r^-$ is a saturation. It remains to be checked that $r^{-*}r^- \succ rr^*$. If $r^{-*}r^-U \between rr^*V$, then $r^-r^{-*}r^-U \between r^*V$ (because $r \cdot|\cdot\, r^-$) and therefore $r^-U \between r^*V$ because r^-r^{-*} is contractive; so $U \between rr^*V$ (again because $r \cdot|\cdot\, r^-$). q.e.d.

We call *representable* a basic topology obtained in this way. Also, we say that a reduction $\mathcal{J}$ is representable if it is of the form rr^* for some relation r. Similarly for a saturation.

[9] This notion can be treated algebraically in the framework of overlap algebras [4, 3, 15]. Classically, it corresponds to the notion of conjugate functions between complete Boolean algebras as studied by Jónsson and Tarski [10].

Proposition 5.2 *For every relation r between two sets X and S, the basic topology $(S, r^{-*}r^{-}, rr^{*})$ is reduced, that is:*

$$\mathbf{A}(rr^{*}) \quad = \quad r^{-*}r^{-} \ .$$

PROOF: Let $\mathcal{A}$ be any other saturation compatible with rr^{*}; we must show that $\mathcal{A} \subseteq r^{-*}r^{-}$. By $r^{-} \dashv r^{-*}$, our claim reduces to $r^{-}\mathcal{A} \subseteq r^{-}$. So let $a \in r^{-}\mathcal{A}U$, that is, $\mathcal{A}U \between r\{a\}$. A general consequence of the adjunction $r \dashv r^{*}$ is that $rr^{*}r = r$ (triangular equality, see [12]); hence $r\{a\} \in Fix(rr^{*})$. Thus we can apply compatibility between $\mathcal{A}$ and rr^{*} to $\mathcal{A}U \between r\{a\}$ and get $U \between r\{a\}$, that is, $a \in r^{-}U$. q.e.d.

So $\mathbf{A}(\mathcal{J})$ can be constructed predicatively at least when $\mathcal{J}$ is representable. One can show that impredicatively every reduction is representable. In fact, let $X = Fix(\mathcal{J})$ and consider the relation r given by: $\mathcal{J}U\, r\, a$ if $a \in \mathcal{J}U$. So $r\{\mathcal{J}U\} = \{a \in S \mid \mathcal{J}U\ r\ a\} = \{a \in S \mid a \in \mathcal{J}U\} = \mathcal{J}U$. We have: $a \in rr^{*}U$ iff $r^{-}\{a\} \between r^{*}U$ iff $(\exists\, \mathcal{J}V \in X)(\mathcal{J}V \in r^{-}\{a\}\ \&\ \mathcal{J}V \in r^{*}U)$ iff $(\exists\, \mathcal{J}V \in X)(a \in r\{\mathcal{J}V\}\ \&\ r\{\mathcal{J}V\} \subseteq U)$ iff $(\exists\, \mathcal{J}V \in X)(a \in \mathcal{J}V\ \&\ \mathcal{J}V \subseteq U)$. Since $\mathcal{J}$ is a reduction, this is tantamount to $a \in \mathcal{J}U$. It is interesting that unfolding the definition of $r^{-*}r^{-}$ in this case one obtains precisely the characterization of $\mathbf{A}(\mathcal{J})$ given in (12). In fact: $a \in r^{-*}r^{-}U$ iff $r^{-}\{a\} \subseteq r^{-}U$ iff $(\forall\, \mathcal{J}V \in X)(\mathcal{J}V \in r^{-}\{a\} \Rightarrow \mathcal{J}V \in r^{-}U)$ iff $(\forall\, \mathcal{J}V \in X)(a \in r\{\mathcal{J}V\} \Rightarrow U \between r\{\mathcal{J}V\})$ iff $(\forall\, \mathcal{J}V \in Fix(\mathcal{J}))(a \in \mathcal{J}V \Rightarrow U \between \mathcal{J}V)$.

5.2 Generated basic topologies

In this section we are going to show that $\mathbf{J}(\mathcal{A})$ can be constructed predicatively for an important class of saturations, namely those which can be generated inductively (see [6]).

In [13] a quite general method is given for generating basic topologies. One starts from a family of sets $\{I(a) \mid a \in S\}$ and subsets $C(a,i) \subseteq S$ for all $a \in S$ and $i \in I(a)$; this is called an *axiom-set*. Next one gives rules to generate the least saturation $\mathcal{A}_{I,C}$ satisfying $a \in \mathcal{A}_{I,C}(C(a,i))$ and, at the same time, the greatest reduction $\mathcal{J}_{I,C}$ which is compatible with $\mathcal{A}_{I,C}$, that is, $\mathbf{J}(\mathcal{A}_{I,C})$ in our terminology. We are going to present such rules, though in a slightly different way, and prove again the main properties of $\mathcal{A}_{I,C}$ and $\mathcal{J}_{I,C}$ given in [13], in particular that $\mathcal{J}_{I,C} = \mathbf{J}(\mathcal{A}_{I,C})$.

We say that a subset $P \subseteq S$ *fulfills the axiom-set* I, C if $C(a,i) \subseteq P \Rightarrow a \in P$ for all $a \in S$ and $i \in I(a)$. For every $U \subseteq S$, let $\mathcal{A}_{I,C}(U)$ be the subset of S defined by the following clauses (see [6]):

1. $U \subseteq \mathcal{A}_{I,C}(U)$;
2. $\mathcal{A}_{I,C}(U)$ fulfills the axiom-set I, C;
3. if $U \subseteq P \subseteq S$ and P fulfills I, C, then $\mathcal{A}_{I,C}(U) \subseteq P$.

In other words, $\mathcal{A}_{I,C}(U)$ is the least subset which contains U and fulfills the axioms. Since subsets fulfilling the axioms are closed under arbitrary intersections (as it is easy to check), we can express $\mathcal{A}_{I,C}(U)$ as:

$$\mathcal{A}_{I,C}(U) \quad = \quad \bigcap\{P \subseteq S \mid U \subseteq P \ \ \& \ \ P \text{ fulfills } I, C\} \ . \tag{22}$$

This shows at once that the operator $\mathcal{A}_{I,C}$ is a saturation, being of the form (9) with respect to the family of all subsets fulfilling the axioms I, C. It also follows that $Fix(\mathcal{A}_{I,C})$ is exactly the collection of subsets fulfilling the axioms.

In [13], the authors propose a dual construction of $\mathcal{J}_{I,C}(V)$ for $V \subseteq S$. Contrary to the construction of $\mathcal{A}_{I,C}U$ which is inductive, the definition of $\mathcal{J}_{I,C}V$ is coinductive. The rules given in [13] say that $\mathcal{J}_{I,C}(V)$ *is the greatest subset of* V *which "splits"* I, C according to the following.

Definition 5.3 *We say that a subset* $Z \subseteq S$ splits the axiom-set I, C *on a set* S *if*

$$a \in Z \Longrightarrow C(a, i) \between Z$$

for all $a \in S$ *and* $i \in I(a)$.

Since splitting subsets are closed under unions, we get:

$$\mathcal{J}_{I,C}(V) \quad = \quad \bigcup\{Z \subseteq S \mid Z \subseteq V \ \ \& \ \ Z \text{ splits } I, C\} \ . \tag{23}$$

This shows that $\mathcal{J}_{I,C}$ is a reduction, namely that which is associated, according to equation (9), with the family of all splitting subsets.

Lemma 5.4 *For every axiom-set* I, C *on* S *and for every* $Z \subseteq S$ *one has:*

$$Z \text{ splits } I, C \qquad \text{if and only if} \qquad Z = \mathcal{J}_{I,C}(Z) \ .$$

Proof: If Z splits I, C, then the union of all splitting subsets contained in Z gives Z itself. Vice versa, recall that $\mathcal{J}_{I,C}(Z)$ splits I, C by definition. q.e.d.

Proposition 5.5 *For every axiom-set* I, C *on a set* S*, the operators* $\mathcal{A}_{I,C}$ *and* $\mathcal{J}_{I,C}$ *are compatible and the basic topology* $(S, \mathcal{A}_{I,C}, \mathcal{J}_{I,C})$ *is saturated, that is:*

$$\mathbf{J}(\mathcal{A}_{I,C}) \quad = \quad \mathcal{J}_{I,C} \ .$$

Proof: In order to show that $\mathcal{A}_{I,C}$ and $\mathcal{J}_{I,C}$ are compatible, let $U, V \subseteq S$ and consider the subset $P = \{a \in S \mid a \in \mathcal{J}_{I,C}V \Rightarrow U \between \mathcal{J}_{I,C}V\}$. Then the instance of compatibility $\mathcal{A}_{I,C}U \between \mathcal{J}_{I,C}V \Rightarrow U \between \mathcal{J}_{I,C}V$ is logically equivalent to $\mathcal{A}_{I,C}U \subseteq P$. Since clearly $U \subseteq P$, in order to obtain $\mathcal{A}_{I,C}U \subseteq P$ using clause 3 of the definition of $\mathcal{A}_{I,C}U$, we only need to show that P fulfills I, C. In other words, we must prove that $U \between \mathcal{J}_{I,C}V$ holds under the assumptions $C(a, i) \subseteq P$ and $a \in \mathcal{J}_{I,C}V$. From $a \in \mathcal{J}_{I,C}V$ one gets $C(a, i) \between \mathcal{J}_{I,C}V$ because $\mathcal{J}_{I,C}V$ splits I, C. Hence also $P \between \mathcal{J}_{I,C}V$ since $C(a, i) \subseteq P$. So there exists $a' \in P$ such that $a' \in \mathcal{J}_{I,C}V$. By the definition of P, this implies that $U \between \mathcal{J}_{I,C}V$.

Finally, let $\mathcal{J}'$ be another reduction which is compatible with $\mathcal{A}_{I,C}$. Since by definition $\mathcal{J}_{I,C}V$ is, for all $V \subseteq S$, the greatest splitting subset contained in V, to prove $\mathcal{J}' \subseteq \mathcal{J}_{I,C}$ it is sufficient to check that $\mathcal{J}'V$ splits I, C. So let $a \in S$, $i \in I(a)$ and assume $a \in \mathcal{J}'V$. By the definition of $\mathcal{A}_{I,C}$ we have $a \in \mathcal{A}_{I,C}(C(a,i))$. So $\mathcal{A}_{I,C}(C(a,i)) \between \mathcal{J}'V$ and hence, by compatibility of $\mathcal{J}'$ and $\mathcal{A}_{I,C}$, $C(a,i) \between \mathcal{J}'V$ as wished. q.e.d.

In other words, $\mathbf{J}(\mathcal{A})$ admits a predicative construction whenever $\mathcal{A}$ can be inductively generated. Note that this is always the case if one works within an impredicative framework. In fact, one can take $I(a) = \{U \subseteq S \mid a \in \mathcal{A}U\}$ and $C(a,U) = U$. In this case, a subset Z splits the axioms precisely when $a \in Z \Rightarrow U \between Z$ for every a and U such that $a \in \mathcal{A}U$. This means $\mathcal{A}U \between Z \Rightarrow U \between Z$ for every U, which says precisely that Z splits $\mathcal{A}$ according to definition 1.6. Thus, as expected, $\mathcal{J}_{I,C}$ defined by (23) coincides with $\mathbf{J}(\mathcal{A})$, as defined by (14).
